Regularized Risk Minimization (RRM)

Find the hypothesis \hat{f} by solving a problem of the form

$$\hat{f} = \arg \min_{f \in \mathcal{F}} \left[\underbrace{\frac{1}{m} \sum_{i=1}^m \ell(f(x_i), y_i)}_{\text{training error}} + \underbrace{\lambda \Omega[f]}_{\text{regularizer}} \right]$$

- \mathcal{F} can be quite a rich hypothesis space.
- The purpose of the regularizer is to avoid overfitting.
- λ is a tunable parameter.
- $\ell(\hat{y}, y)$: loss function
- ℓ might or might not be the same loss as in $\mathcal{E}_{\text{true}}$.

[Tykhonov regularization] [Vapnik 1970's–]

Optimization: equality constraints

Problem:

$$\underset{\mathbf{x} \in \mathbb{R}^n}{\text{minimize}} \quad f(\mathbf{x}) \quad \text{subject to} \quad g(\mathbf{x}) = c.$$

1. Form the **Lagrangian** $L(\mathbf{x}, \lambda) = f(\mathbf{x}) - \lambda (g(\mathbf{x}) - c)$.
2. The solution must be at a critical point of L . \rightarrow Setting

$$\frac{\partial L(\mathbf{x}, \lambda)}{\partial x_i} = 0 \quad i = 1, 2, \dots, n.$$

yields a curve of solutions $\mathbf{x} = \gamma(\lambda)$.

3. Reintroducing the constraint $g(\gamma(\lambda)) = c$ gives λ , hence the optimal \mathbf{x} .

Optimization: inequality constraints

Problem:

$$\underset{\mathbf{x} \in \mathbb{R}^n}{\text{minimize}} \quad f(\mathbf{x}) \quad \text{subject to} \quad g(\mathbf{x}) \geq c.$$

1. Form the **Lagrangian** $L(\mathbf{x}, \lambda) = f(\mathbf{x}) - \lambda (g(\mathbf{x}) - c)$.
2. Introduce the **dual function**

$$h(\lambda) = \inf_{\mathbf{x}} L(\mathbf{x}, \lambda).$$

3. Solve the dual problem

$$\lambda^* = \underset{\lambda}{\operatorname{argmax}} h(\lambda) \quad \text{subject to} \quad \lambda \geq 0.$$

4. The optimal \mathbf{x} is $\inf_{\mathbf{x}} L(\mathbf{x}, \lambda^*)$ (assuming strong duality).

When f is a convex function and $g(\mathbf{x}) \geq c$ defines a convex region of space, this gives the global optimum.

Karush–Kuhn–Tucker conditions

At the optimal solution \mathbf{x}^* of

$$\underset{\mathbf{x} \in \mathbb{R}^n}{\text{minimize}} \quad f(\mathbf{x}) \quad \text{subject to} \quad g(\mathbf{x}) \geq c.$$

either

1. we are on the boundary $\rightarrow g(\mathbf{x}^*) = c$ or
2. we are at an interior point $\rightarrow \lambda^* = 0$.

\rightarrow **Complementary slackness:** $\lambda^* (g(\mathbf{x}^*) - c) = 0$.

Support Vector Machines

Linear classifiers

To apply RRM, go back to binary classification in \mathbb{R}^n with a linear (affine) hyperplane:

Input space: $\mathcal{X} = \mathbb{R}^n$

Output space: $\mathcal{Y} = \{-1, +1\}$

Hypothesis:

$$f(\mathbf{x}) = \mathbf{w} \cdot \mathbf{x} + b.$$

$$h(\mathbf{x}) = \text{sgn}(f(\mathbf{x}))$$

(Note the sneaky difference between f and h)

Question: Of all possible hyperplanes that separate the data which one do we choose?

The margin

Recall, the **margin** of a point (\mathbf{x}, y) to the hyperplane $f(\mathbf{x}) = \mathbf{w} \cdot \mathbf{x} + b = 0$ (with $\|\mathbf{w}\| = 1$) is

$$y (\mathbf{w} \cdot \mathbf{x} + b).$$

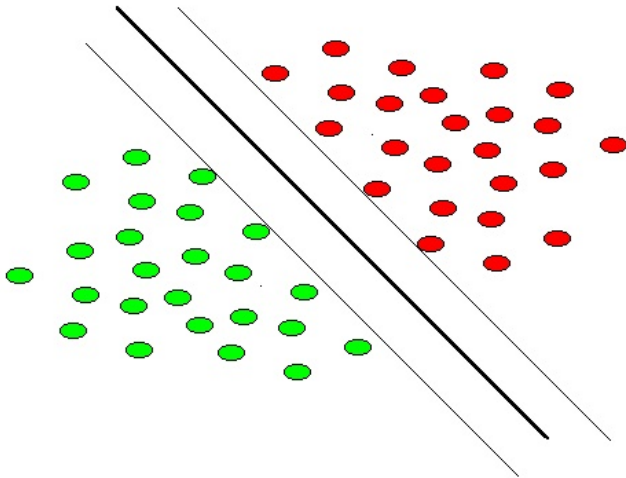

The margin of a dataset $S = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_m, y_m)\}$ to f is

$$\min_i y_i (\mathbf{w} \cdot \mathbf{x}_i + b).$$

In the case of the perceptron we saw that having a large margin is desirable.

IDEA: Choose \mathbf{w} and b explicitly to maximize the margin! \rightarrow **Support Vector Machines (SVM)**

Maximizing the margin

Choose the hyperplane that has the largest margin!

Hard Margin Support Vector Machine

Given a dataset $S = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_m, y_m)\}$,

$$\underset{\|\mathbf{w}\|=1, b}{\text{maximize}} \quad \delta \quad \text{s.t.} \quad y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq \delta \quad \forall i.$$

Equivalent formulation: drop the $\|\mathbf{w}\| = 1$ constraint and solve

$$\underset{\mathbf{w}, b}{\text{minimize}} \quad \frac{1}{2} \|\mathbf{w}\|^2 \quad \text{s.t.} \quad y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1 \quad \forall i.$$

The primal problem

The primal SVM optimization problem

$$\underset{\mathbf{w}, b}{\text{minimize}} \quad \frac{1}{2} \|\mathbf{w}\|^2 \quad \text{s.t.} \quad y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1 \quad \forall i$$

This is a nice convex optimization problem (a QP) with a unique minimum.

→ Introduce a Lagrangian.

From primal to dual

$$\underset{\mathbf{w}, b}{\text{minimize}} \quad \frac{1}{2} \|\mathbf{w}\|^2 \quad \text{s.t.} \quad y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1 \quad \forall i$$

Lagrangian:

$$L(\mathbf{w}, b, \boldsymbol{\alpha}) = \frac{1}{2} \|\mathbf{w}\|^2 - \sum_i \alpha_i (y_i(\mathbf{w} \cdot \mathbf{x}_i + b) - 1)$$

$$\frac{\partial}{\partial w_i} L(\mathbf{w}, b, \boldsymbol{\alpha}) = 0 \quad \Rightarrow \quad \boxed{\mathbf{w} - \sum_i \alpha_i y_i \mathbf{x}_i = 0}$$

$$\frac{\partial}{\partial b} L(\mathbf{w}, b, \boldsymbol{\alpha}) = 0 \quad \Rightarrow \quad \sum_i \alpha_i y_i = 0$$

Dual function:

$$L(\boldsymbol{\alpha}) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j (\mathbf{x}_i \cdot \mathbf{x}_j)$$

The dual problem

The dual SVM optimization problem

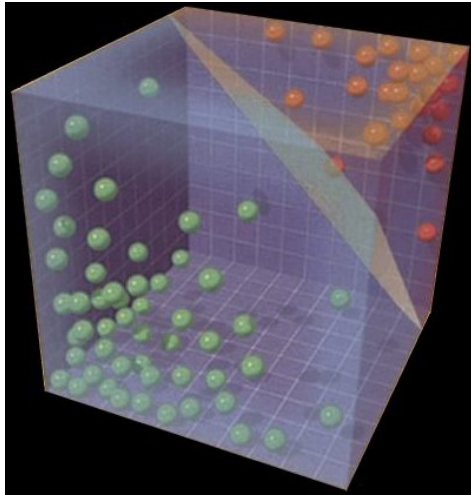

$$\begin{aligned} \underset{\alpha_1, \dots, \alpha_m}{\text{maximize}} \quad & L(\boldsymbol{\alpha}) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j (\mathbf{x}_i \cdot \mathbf{x}_j) \\ \text{subject to} \quad & \sum_i y_i \alpha_i = 0 \quad \text{and} \quad \alpha_i \geq 0 \quad \forall i \end{aligned}$$

Still a QP, but in fewer variables, so easier to solve. In particular,

$$h(\mathbf{x}) = \text{sgn} \left[\sum_i \alpha_i y_i (\mathbf{x} \cdot \mathbf{x}_i) + b \right] = \text{sgn} \left[\sum_i \gamma_i (\mathbf{x} \cdot \mathbf{x}_i) + b \right],$$

where $\gamma_i = y_i \alpha_i$. \rightarrow The solution lies in the span of the data,
 $\mathbf{w} = \sum_i \gamma_i \mathbf{x}_i$.

Support vector machine

Sparsity of support vectors

The KKT conditions prescribe that

$$\alpha_i(y_i(\mathbf{x}_i \cdot \mathbf{w} + b) - 1) = 0 \quad \forall i$$

So $\alpha_i \neq 0$ only for those examples that lie exactly on the margin, and therefore only these “**support vectors**” influence the solution

$$h(\mathbf{x}) = \text{sgn} \left[\sum_i \alpha_i y_i (\mathbf{x} \cdot \mathbf{x}_i) + b \right]$$

→ Sparsity is a precious thing.

Question: But what about non-separable data? → **Soft margin SVMs**

The Soft Margin SVM

The primal SVM optimization problem

$$\underset{\mathbf{w}, b, \xi_1, \dots, \xi_m}{\text{minimize}} \quad \frac{1}{2} \|\mathbf{w}\|^2 + \frac{C}{m} \sum_i \xi_i \quad \text{s.t.} \quad y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1 - \xi_i \quad \xi_i \geq 0 \quad \forall i$$

The ξ_i 's are called **slack variables** and C is a “softness parameter”

[Cortes & Vapnik, 1995]

From primal to dual

$$\underset{\mathbf{w}, b, \xi_1, \dots, \xi_m}{\text{minimize}} \quad \frac{1}{2} \|\mathbf{w}\|^2 + \frac{C}{m} \sum_i \xi_i \quad \text{s.t.} \quad y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1 - \xi_i \quad \xi_i \geq 0 \quad \forall i$$

Lagrangian:

$$L(\mathbf{w}, b, \boldsymbol{\alpha}, \boldsymbol{\beta}) = \frac{1}{2} \|\mathbf{w}\|^2 + \frac{C}{m} \sum_i \xi_i - \sum_i \alpha_i (y_i(\mathbf{w} \cdot \mathbf{x}_i + b) - 1 + \xi_i) - \sum_i \beta_i \xi_i$$

$$\frac{\partial}{\partial w_i} L(\mathbf{w}, b, \boldsymbol{\alpha}, \boldsymbol{\beta}) = 0 \quad \Rightarrow \quad \mathbf{w} - \sum_i \alpha_i y_i \mathbf{x}_i = 0$$

$$\frac{\partial}{\partial b} L(\mathbf{w}, b, \boldsymbol{\alpha}, \boldsymbol{\beta}) = 0 \quad \Rightarrow \quad \sum_i \alpha_i y_i = 0$$

$$\frac{\partial}{\partial \xi_i} L(\mathbf{w}, b, \boldsymbol{\alpha}, \boldsymbol{\beta}) = 0 \quad \Rightarrow \quad \alpha_i + \beta_i = \frac{C}{m}$$

Soft margin SVM dual

The dual SVM optimization problem

$$\begin{aligned} & \underset{\alpha_1, \dots, \alpha_m}{\text{maximize}} \quad L(\boldsymbol{\alpha}) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j (\mathbf{x}_i \cdot \mathbf{x}_j) \\ & \text{subject to} \quad \sum_i y_i \alpha_i = 0 \quad \text{and} \quad 0 \leq \alpha_i \leq \frac{C}{m} \quad \forall i \end{aligned}$$

SVM is just a form of RRM

At the optimum of the primal problem the slacks are as small as possible:

$$\xi_i = \max \{0, 1 - y_i(\mathbf{w} \cdot \mathbf{x}_i + b)\} = \underbrace{(1 - y_i(\mathbf{w} \cdot \mathbf{x}_i + b))}_{\ell_{\text{hinge}}(\mathbf{w} \cdot \mathbf{x}_i, y_i)}_{\geq 0},$$

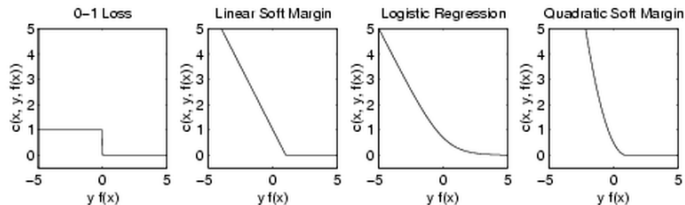

where $(z)_{\geq 0} = \max(0, z)$.

The soft-margin SVM finds

$$\hat{f} = \operatorname{argmin}_{f \in \mathcal{F}} \left[\underbrace{\frac{1}{m} \sum_{i=1}^m \ell_{\text{hinge}}(f(\mathbf{x}_i), y_i)}_{\text{empirical loss}} + \underbrace{\frac{1}{2C} \|\mathbf{w}\|^2}_{\text{regularizer}} \right].$$

where \mathcal{F} is the hypothesis space of $f(x) = \mathbf{w} \cdot \mathbf{x} + b$ linear functions.
